Duke Vascular & Endovascular Surgery

Types of NCS:

Anterior NCS

The LRV is compressed as it passes between the aorta and the SMA

Posterior NCS:

Retro-aortic LRV is compressed between the abdominal aorta and the vertebral column

Atypical NCS

With left IVC, LRV and IVC may be compressed as they pass between the aorta and the SMA

NCS – Imaging (Venography)

NCS – Imaging (CTV)

- CTV advantage:
 - Less costly
 - More familiar to most vascular surgeons

NCS – Imaging (Venography)

- Renal pressure gradient measurement
 - 3 to 10 mm Hg in normal patients
 - 2 to 14 mm Hg in NCS
 - An overlap and area of diagnostic uncertainty if one were to attempt to diagnose NCS by the renal vein pressure gradient alone
- Venous reflux into gonadal and pelvic collaterals. Injection under occlusion pressure into the LRV can cause "retrograde" flow in the gonadal vein.
- We use delayed imaging of selective left renal artery to:
 - Demonstrate unprovoked reflux into gonadal or lumbar veins if present
 - Delineate anatomy of gonadal vein for potential surgical procedure

Angiography

- Selective contrast injection in left renal artery* with delayed imaging of venous outflow
- If direct venous access**; contrast administration w/o presartan injection
 - o IVC, anterior, posterior/pelvic veins
 - o retro-aortic pressure gradient
- *femoral arterial access
- ** femoral venous or internal jugular access

Cross sectional imaging

- MRV* or CTV (abdomen/pelvis)
 - o LRV compression
 - o LRV dilatation (lateral to proximal SMA)
 - o Pelvic venous collaterals
 - o Dilatation of gonadal and/or lumbar veins

**preferred*

Symptoms AND radiologic findings consistent with NCS

Yes → Treatment eligible

No → Investigate for other pathology

272 Velazquez et al **Treatment Modalities** Journal of Vascular Surgery: Venous and Lymphatic Disorders

- All treatment options are directed to reduce venous hypertension
- Treatment modalities ...still evolving...
 - Surgical/open – remains gold standard
 - Surgical/laparoscopic – effective but confined to few centers
 - Endovascular – less effective with higher complications
 - Hybrid – promising, await longer term results

and Meta-Analyses flow diagram for literature selection.

Gonadal Vein Transposition: Technique

- Mini-laparotomy
- Standard retroperitoneal exposure
- Mobilize left GV, dividing all branches
- Left GV divided distally and tunneled behind IMV
- Left GV is reimplanted into IVC

Gonadal Vein Transposition

- Transposing the gonadal vein (transected and re-implanted into the IVC) achieves:
 - Decrease in pelvic congestion
 - Decompression of the LRV **without risk to the kidney**
 - Avoidance of leg incision

Gonadal Vein Transposition for complex Surgical Cases:

Gonadal Vein Transposition for LRVT Redo

- A 30 y.o. F w/PMH of pelvic venous congestion syndrome and NCS s/p bilateral iliac vein stents treated with **left renal vein transposition**.
- **Persistent symptoms at one year:** severe left flank pain and microhematuria.
- Left renal vein remains **compressed**

Gonadal Vein Transposition for LRVT Redo

Successfully treated with LGVT

Posterior NCS

Renal vein transposition much more difficult

Patient successfully treated with left GVT transposition, symptom free

NCS with Complex Anatomy

Journal of Vascular Surgery: Venous and Lymphatic Disorders

CASE REPORT OF THE MONTH

Right gonadal vein transposition for the treatment of anterior nutcracker syndrome in a patient with left-sided inferior vena cava

Joseph M. Williams, MD, and Charles H. Rosen, MD, PhD, Jackson, MS

In this report we describe a patient with anterior nutcracker syndrome (NCS) who was treated with right gonadal vein transposition (RGT) for the treatment of NCS in a patient with left-sided inferior vena cava (IVC). The patient was successfully treated with RGT and remains symptom free at 5-year follow-up.

Nutcracker syndrome (NCS) is a rare clinical entity characterized by compressed inferior vena cava (IVC) between the aorta and the SMA. The IVC is compressed between the aorta and the SMA, which results in retrograde flow of blood in the IVC. The IVC is compressed between the aorta and the SMA, which results in retrograde flow of blood in the IVC. The IVC is compressed between the aorta and the SMA, which results in retrograde flow of blood in the IVC.

How about in patients with complex anatomy?

NCS with Complex Anatomy (left sided IVC)

Journal of Vascular Surgery: Venous and Lymphatic Disorders

CASE REPORT OF THE MONTH

Patient was treated with right GVT, remains symptom free at 5 Years - Working at ATF

In patients with complex anatomy GVT may be the only option

NCS with Concurrent SMA syndrome

Successfully treated with simultaneous LGVT and gastrojejunostomy

The reduction of the aortomesenteric angle and compressed LRV and distal 3rd portion of duodenum

Gonadal Vein Transposition: Duke Experience

From the Eastern Vascular Society

18 pts

Age (years) 30.5 (25.3, 35.7)

Female sex 17 (94.4%)

Race 17:1 Female predilection

Age [Median; Q1, Q3] 30.5; 25.3, 43.5 years

OR time [Median; Q1, Q3] 141; 116, 159 mins

Follow-up [Median; Q1, Q3] 178; 70, 433 days

Symptom Relief: Complete 61.1%
Partial 22.2%
Technical Success 100%

Conclusions: GVT is a safe and effective procedure to treat NCS in patients (93%) with a history (22%) reporting partial symptoms. Age and requires a rigorous and standardized approach to diagnosis and treatment.

Keywords: Gonadal vein transposition Nutcracker syndrome, Pelv

Journal of Vascular Surgery: Venous and Lymphatic Disorders

Left gonadal vein transposition:

- If the diameter/length of the left GV is sufficient
- Proposed as a first approach to treating severe nutcracker syndrome

Summary

- With proper patient selection GVT, LRVT and other surgical and hybrid options is **safe and effective**
- GVT can be tailored to the individual patient's **vascular anatomy** (anterior, posterior), and can be used to treat **complex cases**
